

An OWL Full Interpretation

Jeremy J. Carroll
HP Labs, Bristol, UK

Abstract

This report is an appendix to report HPL-2008-59. It gives a worked example of the construction used in the proof from that report. For finiteness, a reduced datatype map consisting of only `xsd:boolean` is used. Each of the graphs in the construction is listed explicitly, with some redundancy eliminated. The final Herbrand graph contains about 15,000 triples.

1 Introduction

This is an appendix to [1, 2]. The construction in those reports builds a Herbrand graph in which the property extension of every property is totally explicit. This appendix presents a complete worked example.

The construction is essentially an infinite one. We make it finite in the following ways:

- We have a very small datatype map D , being `{ xsd:boolean }`
- We pretend $L_{\text{plain}} = \{ "" \}$
- We use the ter Horst technique of ignoring every `rdf:_i` except the first; these only appear because of their presence in the RDF and RDFS axioms.

The first of these two are non-conformant. Datatype maps are required to include `xsd:string`, `xsd:integer` and `XMLLiteral`. L_{plain} is infinite. The differences are of no great consequence here.

Each section presents one of the graphs in the construction of section 9 of the two papers. Each graph is given by listing the new triples in that graph that were not in the previous triples.

1.1 Notation

In addition to the abbreviations specified in [2], we have the following: `disjointWith`, `intersectionOf`, `equivalentClass`, `minCardinality`, `maxCardinality`, `cardinality`, `differentFrom`, `AllDifferent`, `distinctMembers`, `FunctionalProperty`, `subclassOf`, `allValuesFrom`, `someValuesFrom`, `ContainerMembershipProperty`, `versionInfo`. and `^^xsd:boolean`.

Some of the triples in the first few sections (5 to 8), are shown with a wavy line under, such as (`"0"^^b.type`; eg: c). This means that the triple is not included in the graphs H_i , i.e. sections 9 to 18.

To avoid too much redundancy we also use the following sets of nodes, identified by their first element, with an overline.

<i>Relating to classes</i>	
$\overline{b_{10}}$	$b_{10}, b_9,$
$\overline{\text{Nothing}}$	Nothing, b_2 , DataRange, DataProp, DeprClass, DeprProp, Ontology, Restrict, Alt, Bag, Seq, Statement, XMLLiteral, Container,
$\overline{b_3}$	$b_3, b_6, b_7,$
$\overline{\text{owl:Class}}$	owl:Class, rdfs:Class,
$\overline{\text{ObjProp}}$	ObjProp, Prop,
$\overline{\text{Thing}}$	Thing, Resource,
<i>Relating to properties</i>	
$\overline{b_{11}}$	$b_{11}, b_9,$
$\overline{\text{priorVers}}$	priorVers, allVals, backComp, card, hasValue, imports, incompat, maxCard, minCard, onProperty, someVals, versInfo, $_1$, object, predicate, subject, value, comment, isDefinedBy, label, member, seeAlso,

These are used in *metatriples* like $(\overline{\text{owl:Class}}, \text{equivC}, \overline{\text{owl:Class}})$ in the listing. This one stands for four triples in the graph, by taking each member of the set for both subject and object. Some of these may have occurred earlier in the construction.

2 The initial graph

This is given in section 5. It has several features intended to illustrate the action of the construction on literals, which while somewhat artificial in this example, are part of the D-semantics [3], and covered by our method.

- We use non-canonical lexical forms. The notion of ‘canonical’ used in $\mathcal{V}\mathcal{L}_D$ is not, in general, the same as that in XML Schema [4], which provides several different ‘canonical’ forms for the same value depending on which derived datatype is used. So in general, the literal replacement step between G_3 and H_0 is necessary. In our example, it is artificial.
- We use URI and blank nodes which implicitly represent literals; and then use some of these in predicate position.

3 The Function ψ

The function ψ , see section 9.2 of [2], is determined by some D-interpretation of G_3 . We take ψ to be:

$$\psi(x) = \begin{cases} \text{"true"}^{\wedge\wedge\mathbf{b}} & x = \text{"1"}^{\wedge\wedge\mathbf{b}} \\ \text{"false"}^{\wedge\wedge\mathbf{b}} & x = \text{"0"}^{\wedge\wedge\mathbf{b}} \\ \text{"true"}^{\wedge\wedge\mathbf{b}} & x = \text{eg:v} \\ \text{"false"}^{\wedge\wedge\mathbf{b}} & x = b_{15} \\ x & \text{otherwise} \end{cases} \quad (1)$$

Others would be found from different D-interpretations.

4 The Interpretation

The interpretation in section 10 of [2], uses the graph presented in this document, along with the empty sting, the boolean datatype, and its values as the domain of discourse. The function χ is

then given as:

$$\chi(x) = \begin{cases} \text{the boolean datatype} & x = \text{boolean} \\ "" & x = "" \\ \text{TRUE} & x = \text{"true"}^{\wedge\wedge\text{b}} \\ \text{FALSE} & x = \text{"false"}^{\wedge\wedge\text{b}} \\ x & \text{otherwise} \end{cases} \quad (2)$$

With the last line meaning the occurrences of the appropriate text string in triples (and implicitly in metatriples) in sections 5 to 18, except where deleted by the wavy line. The actual interpretation is built as specified in [2], via the function θ , which we modify, following ter Horst [5] to deal with the `rdf:⊥`:

$$\theta(x) = \begin{cases} \chi(\perp) & x \in \{\text{rdf:}\perp : i = 2, 3 \dots\} \\ \chi(x) & x \in \text{nd}(H_9) \\ \chi(\psi(x)) & x \in \text{nd}(G_3) \end{cases} \quad (3)$$

12 H_3

The nodes of the graph H_2 are: { "", "false"^^b, "true"^^b, b₁, b₂, b₃, b₄, b₅, b₆, b₇, b₈, b₉, b₁₀, b₁₁, b₁₂, eg:a, eg:b, eg:c, eg:p, AllDiff, AnnProp, owl:Class, DataRange, DataProp, DeprClass, DeprProp, FunProp, InvFunProp, Nothing, ObjProp, Ontology, OntProp, Restrict, SymProp, Thing, TransProp, allVals, backComp, card, complmntOf, different, disjoint, dstnctMems, equivC, equivProp, hasValue, imports, incompat, intersect, inverseOf, maxCard, minCard, onProperty, oneOf, priorVers, sameAs, someVals, unionOf, versInfo, Alt, Bag, List, Prop, Seq, Statement, XMLLiteral, _1, first, nil, object, predicate, rest, subject, type, value, rdfs:Class, Container, CMemProp, Datatype, Literal, Resource, comment, domain, isDefinedBy, label, member, range, seeAlso, subClass, subPropOf, boolean, }.

For any single node n in this set, we add (n, sameAs, n) .

For any pair of distinct nodes n, n' in this set, we add $(n, \text{different}, n')$.
